

This is an example of the Felicia font after it has been randomized. Note how after randomization, there are different instances of the same letters depending on whether it is at the beginning of a word, at the end, or in the middle. Note, too, that letters connect much better when following letters which normally connect to the next letter above the baseline, namely "l", "o", "v", and "w". All of these problems were fixed by the randomizes program. The randomizes program makes the proper substitutions at the beginning of words, at the end, and for letter pairs involving "l", "o", "v", and "w". Your handwriting font may also contain multiple versions of common letters like the vowels, and if so the randomizes will substitute in random versions of those letters. Also, if there are any idiosyncrasies in your handwriting, the randomizes can substitute in the correct versions of letters to deal with it. For instance, in the sample of the Hightower font, note that letters with descenders such as "g", "f", "y", etc., are usually followed by letters having an especially long leading stem going underneath the preceding character. But note that this is not the case with the "Kelly" font. The randomizes took care of this automatically.
