

this is an example of the Harsh font after it has been randomized. Note how after randomization, there are different instances of the same letter depending on whether it is at the beginning of a word, at the end, or in the middle. Note, too, that letters connect much better when following letters which normally connect to the next letter above the baseline, namely "b", "o", "u", and "v". All of these problems were fixed by the randomize program. The randomize program makes the proper subdivisions at the beginning of words, and the end, and for letter pairs involving "b", "o", "u", and "v". Your handwriting font may also contain multiple versions of common letters like the vowels, and if so the randomize will subdivide in random versions of those letters. Also, if there are any idiosyncracies in your handwriting, the randomize can subdivide in the correct versions of letters to deal with it. For instance, in the sample of the Hightower font, note that letters with descenders such as "g", "f", "y", etc., are usually followed by letters having an especially low leading stem going underneath the preceding character. But note that this is not the case with the "Keey" font. The randomize tool care of this automatically.
